How Do I Add LCM Types?

In order to add new type definitions to the database and have signals recognized by LCM spy, you need to run the script `gss_rebuilds_types`. This should be located in `~/gss_bin` on your system. It can also be copied from that location from another system.

Generally `~/gss_bin` is added to the system path so the command can be run from anywhere. On a Linux system, this can be done by adding the absolute path to your `rc.local` file.
